

LAUNCH TERMS, MADE VERIFIABLE

# Every token launch has a story. Read the contract.

A disclosure and verification layer for Meteora Dynamic Bonding Curve launches.

DBC

# The launch promise is easy to make. Hard to verify.

DBC lets builders set fees, curves, migration rules, liquidity distribution and token authority. Those choices are on-chain, but buried in program accounts.

01

## Opaque terms

People cannot easily read all launch settings in one place.

02

## Static claims

Screenshots and posts do not update as a pool changes.

03

## No attribution

A shared document rarely proves the launch owner signed it.

# Inspect. Simulate. Attest. Verify.

DBC pool / config

Meteora SDK

Readable terms

Signed covenant

|                     |    |
|---------------------|----|
| Initial trading fee | 2% |
|---------------------|----|

|                   |               |
|-------------------|---------------|
| Graduation target | 8,696.94 USDC |
|-------------------|---------------|

|           |         |
|-----------|---------|
| Migration | DAMM v2 |
|-----------|---------|

A launch owner selects exact on-chain claims and signs them with a DBC role wallet. Any visitor can import the file, verify the Ed25519 signature and compare every field with a fresh read.

Example values from a live public mainnet pool. Not a product endorsement.

# Meteora runs through the core.

- Official SDK decodes standard and transfer-hook DBC pools and configs.
- Scenario lab calls **swapQuote2** with fresh reserves and partial-fill mode.
- Role verification checks signer against the DBC fee claimer or pool creator.
- Raw token units use exact integer arithmetic.

Read-only. No funds or wallet needed to inspect and simulate.

# A trust layer for **every** launch.

Launch studios design the token. Screeners find the pool. **Curve Covenant makes its claims checkable.**

## Monitor

Future paid alerts and compliance tooling

Integration and paid monitoring are product plans, not existing revenue or partnerships.

# Already running on **mainnet data.**

A real DBC pool can be inspected and quoted in the browser. The source, tests and deployment are public. Signed disclosures can be checked against on-chain roles.
